

namely those who have specialized in "narrow" fields. For example, if one has limited knowledge of molecular physics (as has this reviewer) or semiconductors, this book offers a good, quick introduction and survey of the subject(s). On this positive note, let me briefly skim the highlights of *Modern Physics*.

Modern Physics presents a study of elementary phenomena in nuclei, atoms, molecules, and solids in the light of quantum mechanics. The first chapter gives a historic overview of experiments and results that led to the discovery of the atom, its structure, mass, and charge, at the same time describing elementary properties of particles composing atoms and nuclei. Chapter 2 deals with the behavior of assemblies of particles, introducing the ideal gas law, the Maxwellian distribution of kinetic energies and velocities of these particles, and the Boltzmann distribution.

Since classical mechanics and electromagnetic theory could not explain all the properties of atoms, it became apparent that particles show some different phenomena in behavior that could only be understood by means of quantum physics. Chapter 3 describes the ways that led to modern theories of quantum physics, starting with the explanation of black body radiation, the photoelectric effect, the discrete nature of atomic spectra, electron diffraction in crystals and other phenomena that all confirmed the dual nature of subatomic particles and electromagnetic radiation. Chapter 4 gives the mathematical background of quantum mechanics. It introduces the Schrodinger equation and shows how it can be applied to describe and explain the different physical phenomena of the world of modern physics. In Chap. 5, the Schrodinger equation is solved for the hydrogen atom and the quantum numbers are introduced. Applying Pauli's principle of exclusion, the electronic structure of atoms is then explained. Chapters 6 and 7 deal with chemical bonds in the light of wave mechanics—the molecular binding and spectra, the ionic bonds, the metallic bonds, and energy bands in solids.

Next, in Chap. 8, the theory of binding and energy bands is used to explain selected properties of solids, such as the electrical conductivity in metals, the thermal conductivity in solids, and the magnetic properties of materials. Chapter 9 explores how imperfections and impurities in crystals affect the physical properties of solids, and the next chapter makes use of the theories that have been introduced to study semiconductors.

The last two chapters are devoted to nuclear physics. The quantum physics explanation of natural radioactivity, nuclear reactions, and nuclear forces is first given, while Chap. 12 deals with the applications of nuclear reactions and radionuclides in practice and with the interactions of radiation with matter.

J. N. Anno received his PhD in physics from The Ohio State University in 1965. Since 1953, when he joined the staff of Battelle Memorial Institute, Columbus Laboratories, he has been involved primarily in nuclear-oriented research and development. He was operating supervisor of the Battelle Research Reactor from 1955 to 1960, then continued later research in the effects of radiation on materials, covering a broad spectrum of topics from secondary electron emission to radiation-induced desorption. In 1970, Dr. Anno joined the nuclear engineering faculty at the University of Cincinnati, where he is now teaching and performing research primarily in the areas of nuclear physics, radiation effects, and fusion. He is also president of

This book has four major parts: basic heat transfer theory as applicable to problems encountered in dealing with foods and agricultural materials, methods for determining thermophysical properties, applications to food heat transfer problems, and finally a large appendix of property values.

There is nothing particularly profound about the material in this book. It is taken piece by piece from the literature with a stress on the data. Where appropriate, there are also brief descriptions of the original investigator's techniques. Very little space is devoted to critically reviewing the data or the experiments from which they came.

There are some discrepancies in the cited references, and a number of typographical errors and poorly labeled figures are apparent. In the selection of subject matter, it appears odd that there is no space devoted to freeze-dried materials. This type of food processing is energy intensive and design predictions depend heavily on having accurate property values.

Most nuclear engineers would not find this book of much help unless they were directly involved in the food processing industry.

Clifford J. Cremers is presently professor and chairman of the Department of Mechanical Engineering at the University of Kentucky, where he has been since 1966. Previous to that he was on the faculty at the Georgia Institute of Technology, where he went after receiving a PhD from the University of Minnesota in 1964. He teaches courses across the spectrum of the thermal sciences and has published over 60 papers in heat transfer in plasma systems, heat transfer in frost layers, and thermophysical property measurement.
